

SPLIT Function (VB work-a-like)

The Split() function cuts a string at specific points, returning the resultant sub-strings in an array and returns the highest dimension of the array.

The elements of the array are the delimited sub-strings of the input string. e.g.

```
x=Split("fred,jim,sheila","","")
```

will break the string at each

```
" , "
```

return x=3 and the three sub-strings

```
"fred"
```

```
,
```

```
"jim"
```

&

```
"sheila"
```

in elements 1,2 & 3 of the string array.

Behaviour:

The sub-strings are always returned in the array

```
SP$
```

. It is not currently possible to specify another Array. Split() trashes the passed-in string - if this is a problem consider [this method](#). If no delimiter is found, Split() returns 1 - with

```
SP$(1)
```

as the entire string. Sub-strings are not trimmed in any way. The delimiter can be any length>0. Performing the Split() on the above string, specifying

```
"jim"
```

as the delimiter would return two elements

```
"fred,"
```

and

```
",sheila"
```

. The delimiter does not form any part of the sub-strings.

Compatible with all versions of MMBasic.

Syntax:

```
NumOfElements=Split(StringToSplit, delimiter)
```

Example usage:

```
z=Split(Time$,:")
FOR n=1 TO z
    PRINT n,SP$(n)
NEXT
```

The Code:

```
Function Split(a$,b$) As Integer' returns the number of dimensions in SP$
always starts from 1 regardless of OPTION BASE
  Local Integer z,n,m
  If b$="" Then Split=0:Exit Function ' can't split with an empty
delimiter

  ' if SP$ doesn't exist, the ERASE will cause an error, choose which ON
ERROR SKIP you need

'MM.Ver <5.04
  On Error Skip
'MM.Ver >=5.04
  On Error Skip 1

  Erase SP$
  z=1:n=0
  Do 'count instances of delimiter for DIM SP$()
    z=Instr(z,a$,b$)
    If z=0 Then
      If n=0 Then ' no delimiters
        Dim SP$(1):SP$(1)=a$:Split=1:Exit Function ' only one substring
      Else
        Exit Do
      End If
    Else
      n=n+1:z=z+Len(b$)
    End If
  Loop

  m=n+1:n=1
```

```
Dim SP$(m)
Do
    z=Instr(1,a$,b$)
    If z=0 Then
        SP$(m)=a$:Exit Do
    Else
        SP$(n)=Left$(a$,z-1):a$=Mid$(a$,z+Len(b$)):n=n+1
    End If
Loop
Split=m
End Function
```

The [cField\\$](#) CFunction extracts individual fields from a string in real-time rather than splitting and you might consider this as it offers advantages of speed and memory over Split() but has some limitations in that an empty string is returned if the delimiter is not found and there is no way of telling the number of substrings.
